Computing

is Bottlenecked by Data

# Data is Key for AI, ML, Genomics, ...

---

- Important workloads are all data intensive
- They require rapid and efficient processing of large amounts of data
- Data is increasing
  - We can generate more than we can process
  - We need to perform more sophisticated analyses on more data

# Huge Demand for Performance & Efficiency

## Exponential Growth of Neural Networks

Memory and compute requirements

**1800x more compute**  
In just 2 years

Tomorrow, **multi-trillion**  
parameter models

**~4 orders of magnitude increase**  
in memory requirement  
in just a few years!

# Huge Demand for Performance & Efficiency

development of new sequencing technologies

Oxford Nanopore MinION

Number of Genomes Sequenced

The Economist

# The Problem

---

Data access is the major performance and energy bottleneck

Our current  
design principles  
cause great energy waste  
(and great performance loss)

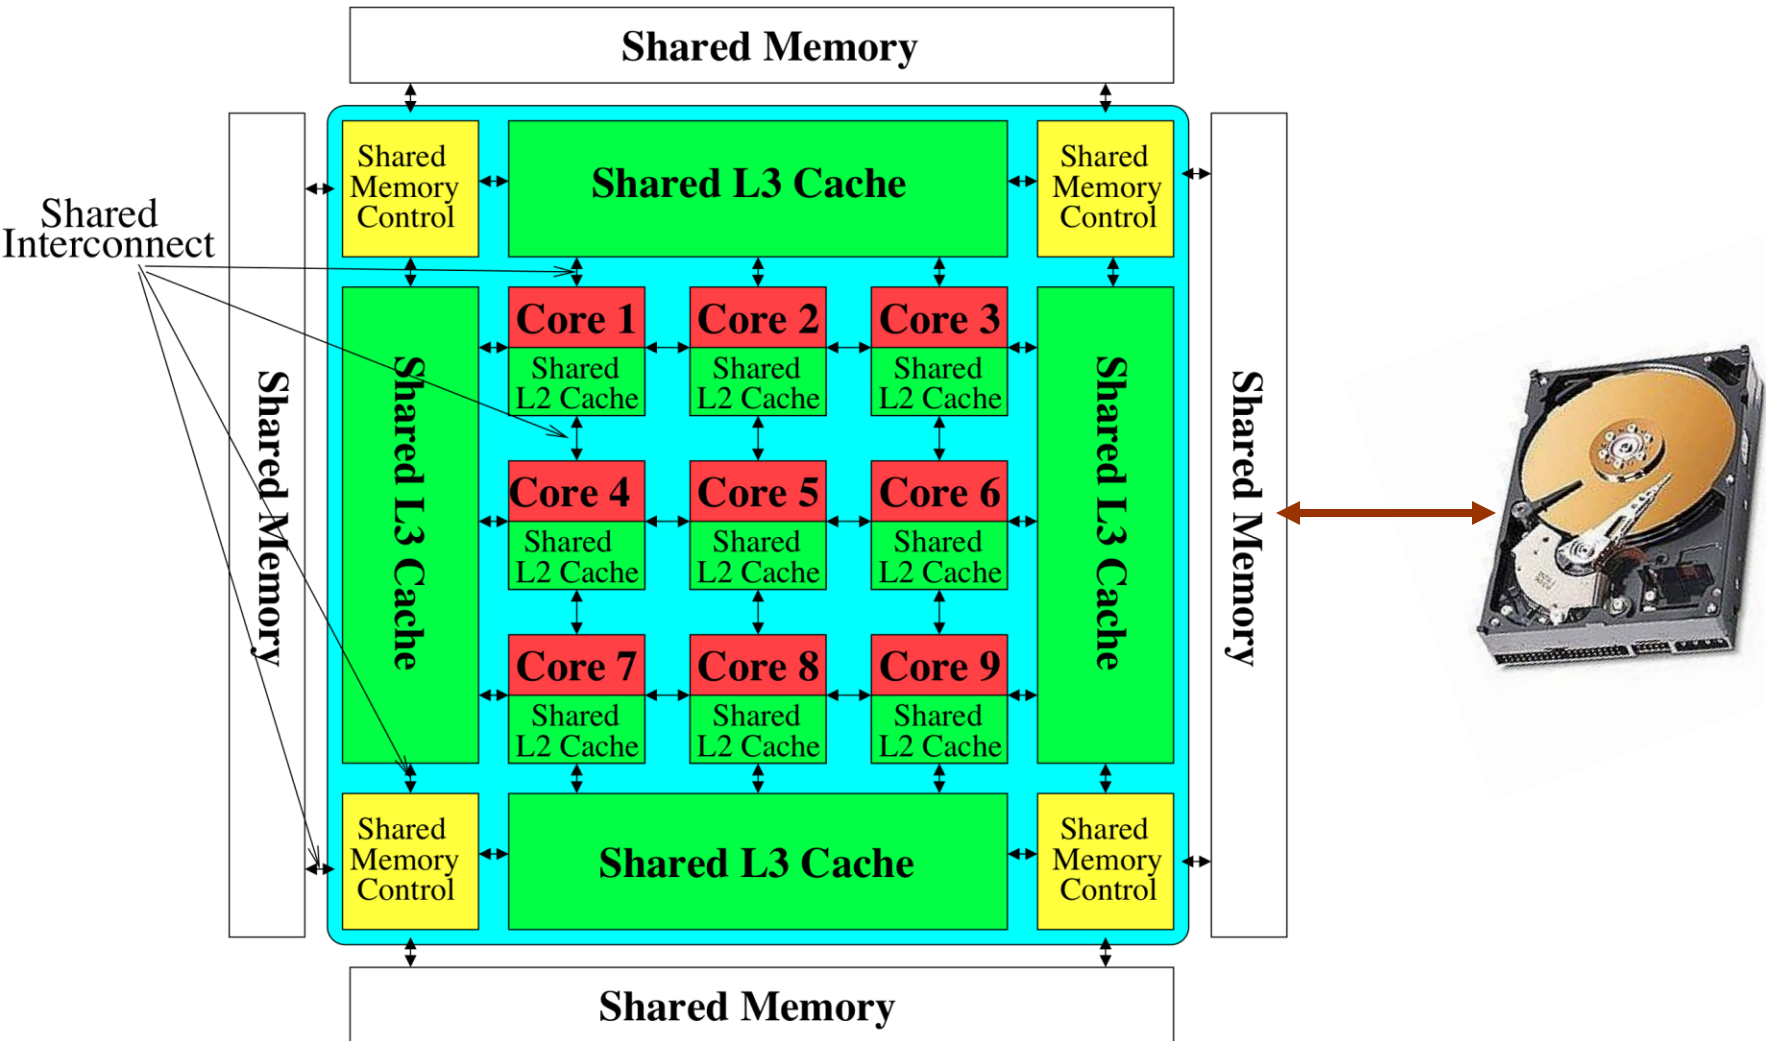

# Today's Computing Systems

---

- Processor centric
- All data processed in the processor → at great system cost

# Perils of Processor-Centric Design

**Most of the system is dedicated to storing and moving data**

**Yet, system is still bottlenecked by memory**

# Processor-Centric System Performance

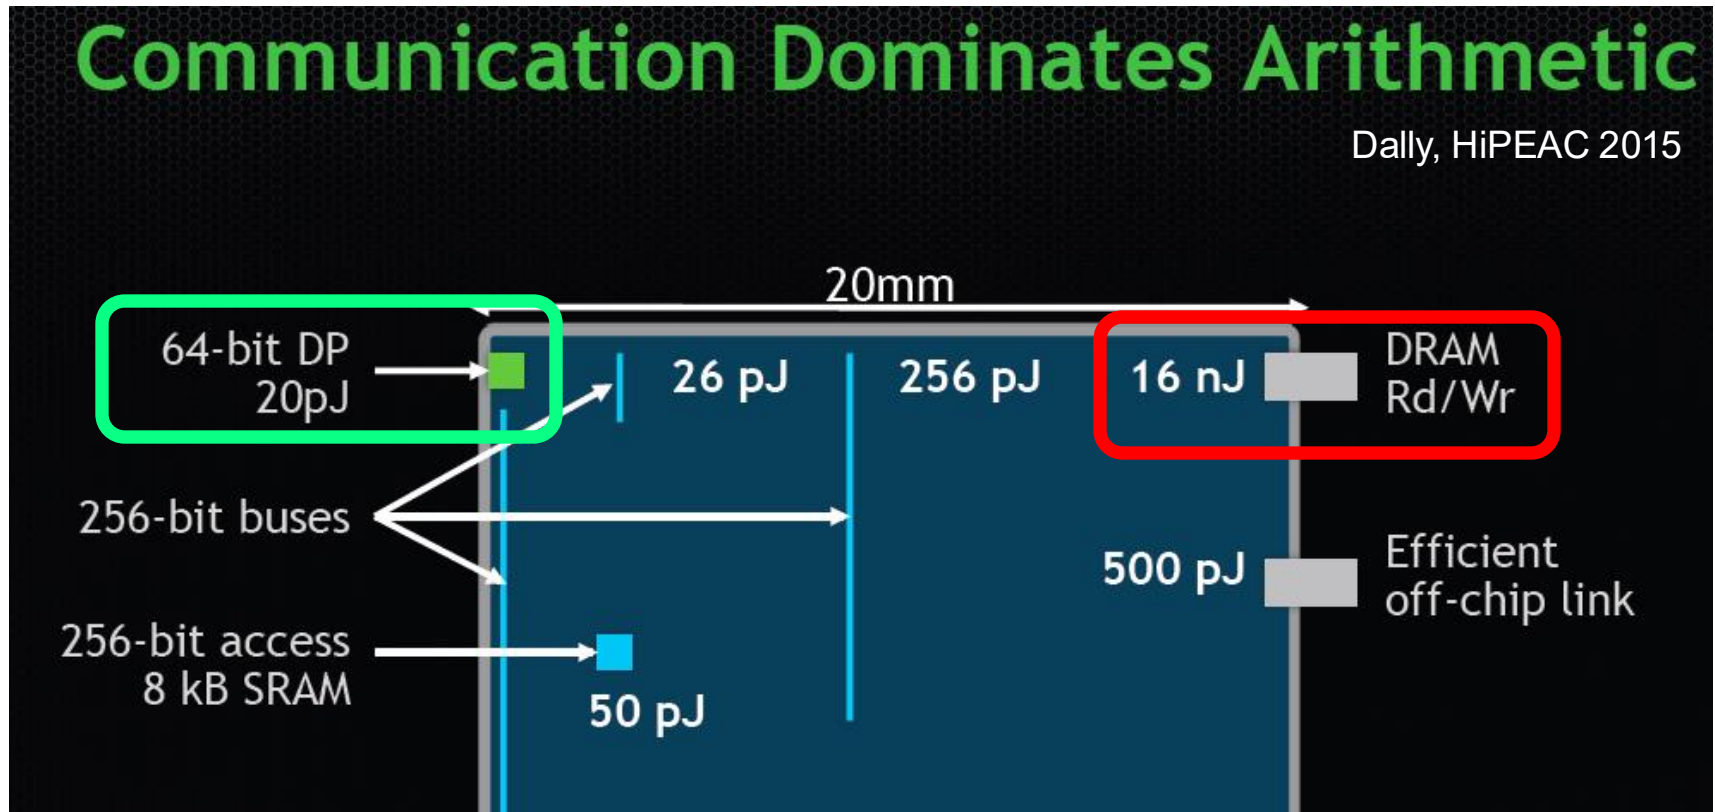

- All of Google's Data Center Workloads (2015):

# Data Movement vs. Computation Energy

## Communication Dominates Arithmetic

Dally, HiPEAC 2015

A memory access consumes  $\sim 100\text{-}1000\times$  the energy of a complex addition

# Data Movement vs. Computation Energy

# Data Movement vs. Computation Energy

A memory access consumes 6400X the energy of a simple integer addition

# Energy Waste in Mobile Devices

# Processing in/near Memory: An Old Idea

- Kautz, "Cellular Logic-in-Memory Arrays", IEEE TC 1969.

IEEE TRANSACTIONS ON COMPUTERS, VOL. C-18, NO. 8, AUGUST 1969

## Cellular Logic-in-Memory Arrays

WILLIAM H. KAUTZ, MEMBER, IEEE

**Abstract**—As a direct consequence of large-scale integration, many advantages in the design, fabrication, testing, and use of digital circuitry can be achieved if the circuits can be arranged in a two-dimensional iterative, or cellular, array of identical elementary networks, or cells. When a small amount of storage is included in each cell, the same array may be regarded either as a logically enhanced memory array, or as a logic array whose elementary gates and connections can be "programmed" to realize a desired logical behavior.

In this paper the specific engineering features of such cellular logic-in-memory (CLIM) arrays are discussed, and one such special-purpose array, a cellular sorting array, is described in detail to illustrate how these features may be achieved in a particular design. It is shown how the cellular sorting array can be employed as a single-address, multiword memory that keeps in order all words stored within it. It can also be used as a content-addressed memory, a pushdown memory, a buffer memory, and (with a lower logical efficiency) a programmable array for the realization of arbitrary switching functions. A second version of a sorting array, operating on a different sorting principle, is also described.

**Index Terms**—Cellular logic, large-scale integration, logic arrays logic in memory, push-down memory, sorting, switching functions.

$$\begin{aligned}\hat{x} &= \bar{w}x + wy \\ s_y &= wcx, r_y = wc\bar{x} \\ \hat{z} &= M(x, \bar{y}, z) = x\bar{y} + z(x + \bar{y})\end{aligned}$$

Fig. 1. Cellular sorting array I.

# Processing in/near Memory: An Old Idea

---

- Stone, “A Logic-in-Memory Computer,” IEEE TC 1970.

## A Logic-in-Memory Computer

HAROLD S. STONE

*Abstract*—If, as presently projected, the cost of microelectronic arrays in the future will tend to reflect the number of pins on the array rather than the number of gates, the logic-in-memory array is an extremely attractive computer component. Such an array is essentially a microelectronic memory with some combinational logic associated with each storage element.

# Why In-Memory Computation Today?

---

- **Huge demand from Applications & Systems**
  - ❑ Data access bottleneck
  - ❑ Energy & power bottlenecks
  - ❑ Data movement energy dominates computation energy
  - ❑ Need all at the same time: performance, energy, sustainability
  - ❑ We can improve all metrics by minimizing data movement
- **Huge problems with Memory Technology**
  - ❑ Memory technology scaling is not going well (e.g., RowHammer)
  - ❑ Many scaling issues demand intelligence in memory
  - ❑ Emerging technologies can enable new functions in memory
- **Designs are squeezed in the middle**

# Industry's Intelligent DRAM Controllers (II)

---

SK hynix Semiconductor, Icheon, Korea

DRAM products have been recently adopted in a wide range of high-performance computing applications: such as in cloud computing, in big data systems, and IoT devices. This demand creates larger memory capacity requirements, thereby requiring aggressive DRAM technology node scaling to reduce the cost per bit [1,2]. However, DRAM manufacturers are facing technology scaling challenges due to row hammer and refresh retention time beyond 1a-nm [2]. Row hammer is a failure mechanism, where repeatedly activating a DRAM row disturbs data in adjacent rows. Scaling down severely threatens reliability since a reduction of DRAM cell size leads to a reduction in the intrinsic row hammer tolerance [2,3]. To improve row hammer tolerance, there is a need to probabilistically activate adjacent rows with carefully sampled active addresses and to improve intrinsic row hammer tolerance [2]. In this paper, row-hammer-protection and refresh-management schemes are presented to guarantee DRAM security and reliability despite the aggressive scaling from 1a-nm to sub 10-nm nodes. The probabilistic-aggressor-tracking scheme with a refresh-management function (RFM) and per-row hammer tracking (PRHT) improve DRAM resilience. A multi-step precharge reinforces intrinsic row-hammer tolerance and a core-bias modulation improves retention time: even in the face of cell-transistor degradation due to technology scaling. This comprehensive scheme leads to a reduced probability of failure, due to row hammer attacks, by 93.1% and an improvement in retention time by 17%.

Version 1.30

This standard defines the DDR5 SDRAM specification, including features, functionalities, AC and DC characteristics, packages, and ball/signal assignments. The purpose of this Standard is to define the minimum set of requirements for JEDEC compliant 8 Gb through 32 Gb for x4, x8, and x16 DDR5 SDRAM devices. This standard was created based on the DDR4 standards (JESD79-4) and some aspects of the DDR, DDR2, DDR3, and LPDDR4 standards (JESD79, JESD79-2, JESD79-3, and JESD209-4).

**Abstract**—CXL interface is the up-to-date technology that enables effective memory expansion by providing a memory-sharing protocol in configuring heterogeneous devices. However, its limited physical bandwidth can be a significant bottleneck for emerging data-intensive applications. In this work, we propose a novel CXL-based memory disaggregation architecture with a real-world prototype demonstration, which overcomes the bandwidth limitation of the CXL interface using near-data processing. The experimental results demonstrate that our design achieves up to  $1.9\times$  better performance/power efficiency than the existing CPU system.

**Index Terms**—Compute express link (CXL), near-data-processing (NDP)

**Abstract**—Our ISCA 2015 paper [1] provides a new programmable processing-in-memory (PIM) architecture and system design that can accelerate key data-intensive applications, with a focus on graph processing workloads. Our major idea was to completely rethink the system, including the programming model, data partitioning mechanisms, system support, instruction set architecture, along with near-memory execution units and their communication architecture, such that an important workload can be accelerated at a maximum level using a distributed system of well-connected near-memory accelerators. We built our accelerator system, Tesseract, using 3D-stacked memories with logic layers, where each logic layer contains general-purpose processing cores and cores communicate with each other using a message-passing programming model. Cores could be specialized for graph processing (or any other application to be accelerated).

To our knowledge, our paper was the first to completely design a near-memory accelerator system from scratch such that it is both generally programmable and specifically customizable to accelerate important applications, with a case study on major graph processing workloads. Ensuing work in academia and industry showed that similar approaches to system design can greatly benefit both graph processing workloads and other applications, such as machine learning, for which ideas from Tesseract seem to have been influential.

This short retrospective provides a brief analysis of our ISCA 2015 paper and its impact. We briefly describe the major ideas and contributions of the work, discuss later works that built on it or were influenced by it, and make some educated guesses on what the future may bring on PIM and accelerator systems.

### I. BACKGROUND, APPROACH & MINDSET

We started our research when 3D-stacked memories (e.g., [2–4]) were viable and seemed to have promise for building effective and practical processing-near-memory systems. Such near-memory systems could lead to improvements, but there was little to no research that examined how an accelerator could be completely (re-)designed using such near-memory technology, from its hardware architecture to its programming model and software system, and what the performance and energy benefits could be of such a re-design. We set out to answer these questions in our ISCA 2015 paper [1].

We followed several major principles to design our accelerator from the ground up. We believe these principles are still important: a major contribution and influence of our work was in putting all of these together in a cohesive full-system design and demonstrating the large performance and energy benefits that can be obtained from such a design. We see a similar approach in many modern large-scale accelerator systems in machine learning today (e.g., [5–9]). Our principles are:

1. *Near-memory execution* to enable/exploit the high data access bandwidth modern workloads (e.g., graph processing) need and to reduce data movement and access latency.

2. *General programmability* so that the system can be easily adopted, extended, and customized for many workloads.

3. *Maximal acceleration capability* to maximize the performance and energy benefits. We set ourselves free from backward compatibility and cost constraints. We aimed to completely re-design the system stack. Our goal was to explore the maximal performance and energy efficiency benefits we can gain from a near-memory accelerator if we had complete freedom to change things as much as we needed. We contrast this approach to the *minimal intrusion* approach we also explored in a separate ISCA 2015 paper [10].

4. *Customizable to specific workloads*, such that we can maximize acceleration benefits. Our focus workload was graph

analytics/processing, a key workload at the time and today. However, our design principles are not limited to graph processing and the system we built is customizable to other workloads as well, e.g., machine learning, genome analysis.

5. *Memory-capacity-proportional performance*, i.e., processing capability should proportionally grow (i.e., scale) as memory capacity increases and vice versa. This enables scaling of data-intensive workloads that need both memory and compute.

6. *Exploit new technology (3D stacking)* that enables tight integration of memory and logic and helps multiple above principles (e.g., enables customizable near-memory acceleration capability in the logic layer of a 3D-stacked memory chip).

7. *Good communication and scaling capability* to support scalability to large dataset sizes and to enable memory-capacity-proportional performance. To this end, we provided scalable communication mechanisms between execution cores and carefully interconnected small accelerator chips to form a large distributed system of accelerator chips.

8. *Maximal and efficient use of memory bandwidth* to supply the high-bandwidth data access that modern workloads need. To this end, we introduced new, specialized mechanisms for prefetching and a programming model that helps leverage application semantics for hardware optimization.

### II. CONTRIBUTIONS AND INFLUENCE

We believe the major contributions of our work were 1) complete rethinking of how an accelerator system should be designed to enable maximal acceleration capability, and 2) the design and analysis of such an accelerator with this mindset and using the aforementioned principles to demonstrate its effectiveness in an important class of workloads.

One can find examples of our approach in modern large-scale machine learning (ML) accelerators, which are perhaps the most successful incarnation of scalable near-memory execution architectures. ML infrastructure today (e.g., [5–9]) consists of accelerator chips, each containing compute units and high-bandwidth memory chips tightly packaged together, and features scale-up capability enabled by connecting thousands of such chips with high-bandwidth interconnection links. The system-wide rethinking that was done to enable such accelerators and many of the principles used in such accelerators resemble our ISCA 2015 paper’s approach.

The “memory-capacity-proportional performance” principle we explored in the paper shares similarities with how ML workloads are scaled up today. Similar to how we carefully sharded graphs across our accelerator chips to greatly improve effective memory bandwidth in our paper, today’s ML workloads are sharded across a large number of accelerators by leveraging data/model parallelism and optimizing the placement to balance communication overheads and compute scalability [11, 12]. With the advent of large generative models requiring high memory bandwidth for fast training and inference, the scaling behavior where capacity and bandwidth are scaled together has become an essential architectural property to support modern data-intensive workloads.

The “maximal acceleration capability” principle we used in Tesseract provides much larger performance and energy improvements and better customization than the “minimalist” approach that our other ISCA 2015 paper on *PIM-Enabled Instructions* [10] explored: “minimally change” an existing

system to incorporate (near-memory) acceleration capability to ease programming and keep costs low. So far, the industry has more widely adopted the maximal approach to overcome the pressing scaling bottlenecks of major workloads. The key enabler that bridges the programmability gap between the maximal approach favoring large performance & energy benefits and the minimal approach favoring ease of programming is compilation techniques. These techniques lower well-defined high-level constructs into lower-level primitives [12, 13]; our ISCA 2015 papers [1, 10] and a follow-up work [14] explore them lightly. We believe that a good programming model that enables large benefits coupled with support for it across the entire system stack (including compilers & hardware) will continue to be important for effective near-memory system and accelerator designs [14]. We also believe that the maximal versus minimal approaches that are initially explored in our two ISCA 2015 papers is a useful way of exploring emerging technologies (e.g., near-memory accelerators) to better understand the tradeoffs of system designs that exploit such technologies.

### III. INFLUENCE ON LATER WORKS

Our paper was at the beginning of a proliferation of scalable near-memory processing systems designed to accelerate key applications (see [15] for many works on the topic). Tesseract has inspired many near-memory system ideas (e.g., [16–28]) and served as the de facto comparison point for such systems, including near-memory graph processing accelerators that built on Tesseract and improved various aspects of Tesseract. Since machine learning accelerators that use high-bandwidth memory (e.g., [5, 29]) and industrial PIM prototypes (e.g., [30–41]) are now in the market, near-memory processing is no longer an “eccentric” architecture it used to be when Tesseract was originally published.

Graph processing & analytics workloads remain as an important and growing class of applications in various forms, ranging from large-scale industrial graph analysis engines (e.g., [42]) to graph neural networks [43]. Our focus on large-scale graph processing in our ISCA 2015 paper increased attention to this domain in the computer architecture community, resulting in subsequent research on efficient hardware architectures for graph processing (e.g., [44–46]).

### IV. SUMMARY AND FUTURE OUTLOOK

We believe that our ISCA 2015 paper’s principled rethinking of system design to accelerate an important class of data-intensive workloads provided significant value and enabled/influenced a large body of follow-on works and ideas. We expect that such rethinking of system design for key workloads, especially with a focus on “maximal acceleration capability,” will continue to be critical as pressing technology and application scaling challenges increasingly require us to think differently to substantially improve performance and energy (as well as other metrics). We believe the principles exploited in Tesseract are fundamental and they will remain useful and likely become even more important as systems become more constrained due to the continuously-increasing memory access and computation demands of future workloads. We also project that as hardware substrates for near-memory acceleration (e.g., 3D stacking, in-DRAM computation, NVM-based PIM, processing using memory [15]) evolve and mature, systems will take advantage of them even more, likely using principles similar to those used in the design of Tesseract.

# MIMDRAM: More Flexible Processing using DRAM

---

- **Appears at HPCA 2024**    <https://arxiv.org/pdf/2402.19080.pdf>

## **MIMDRAM: An End-to-End Processing-Using-DRAM System for High-Throughput, Energy-Efficient and Programmer-Transparent Multiple-Instruction Multiple-Data Computing**

Geraldo F. Oliveira<sup>†</sup>    Ataberk Olgun<sup>†</sup>    Abdullah Giray Yağlıkçı<sup>†</sup>    F. Nisa Bostancı<sup>†</sup>  
Juan Gómez-Luna<sup>†</sup>    Saugata Ghose<sup>‡</sup>    Onur Mutlu<sup>†</sup>

<sup>†</sup> *ETH Zürich*

<sup>‡</sup> *Univ. of Illinois Urbana-Champaign*

*Our **goal** is to design a flexible PUD system that overcomes the limitations caused by the large and rigid granularity of PUD. To this end, we propose MIMDRAM, a hardware/software co-designed PUD system that introduces new mechanisms to allocate and control only the necessary resources for a given PUD operation. The key idea of MIMDRAM is to leverage fine-grained DRAM (i.e., the ability to independently access smaller segments of a large DRAM row) for PUD computation. MIMDRAM exploits this key idea to enable a multiple-instruction multiple-data (MIMD) execution model in each DRAM subarray (and SIMD execution within each DRAM row segment).*

# MIMDRAM: Key Idea

Enable narrower-width operations than a DRAM row

Use fine-grained DRAM for processing-using-DRAM:

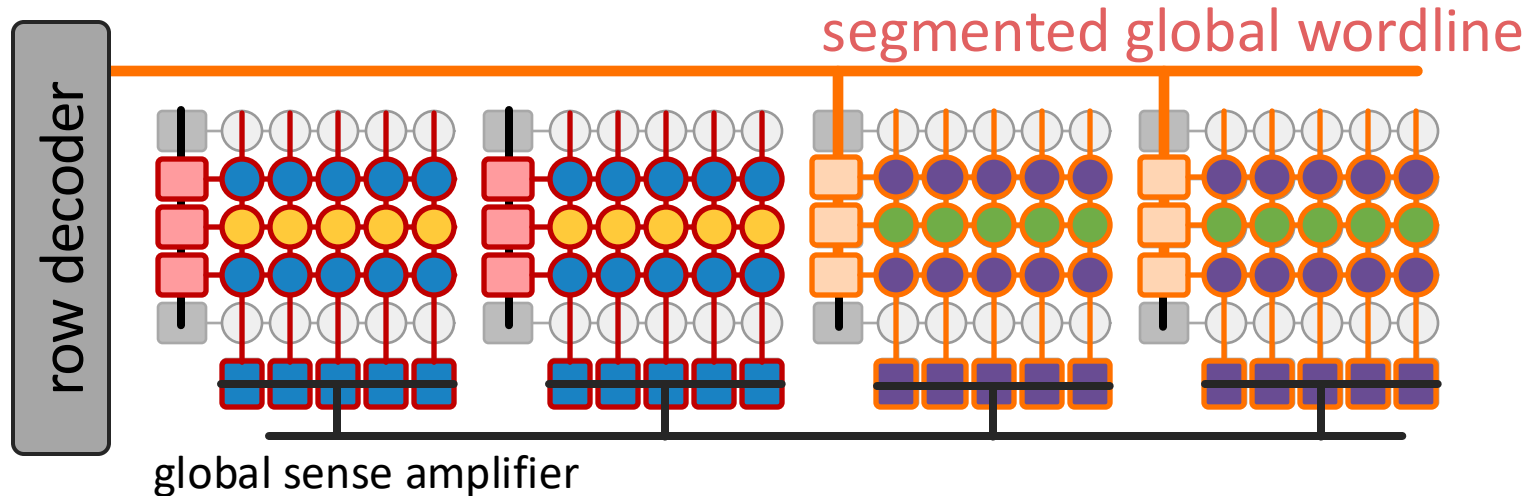

## 1 Improves SIMD utilization

- for a single PUD operation, only access the DRAM mats with target data

# MIMDRAM: Key Idea

Enable narrower-width operations than a DRAM row

Use fine-grained DRAM for processing-using-DRAM:

## 1 Improves SIMD utilization

- for a single PUD operation, only access the DRAM mats with target data
  - for multiple PUD operations, execute independent operations concurrently
- **multiple instruction, multiple data (MIMD) execution model**

# Sectored DRAM

A. Giray Yağlıkcı<sup>§</sup>      Hasan Hassan<sup>§</sup>      Oğuz Ergin<sup>†</sup>      Onur Mutlu<sup>§</sup>

# MIMDRAM: Key Idea

Enable narrower-width operations than a DRAM row

Use fine-grained DRAM for processing-using-DRAM:

## 1 Improves SIMD utilization

- for a single PUD operation, only access the DRAM mats with target data
- for multiple PUD operations, execute independent operations concurrently  
→ multiple instruction, multiple data (MIMD) execution model

## 2 Enables low-cost interconnects for vector reduction

- global and local data buses can be used for inter-/intra-mat communication

# MIMDRAM: Key Idea

Enable narrower-width operations than a DRAM row

Use fine-grained DRAM for processing-using-DRAM:

## 1 Improves SIMD utilization

- for a single PUD operation, only access the DRAM mats with target data
- for multiple PUD operations, execute independent operations concurrently  
→ multiple instruction, multiple data (MIMD) execution model

## 2 Enables low-cost interconnects for vector reduction

- global and local data buses can be used for inter-/intra-mat communication

## 3 Eases programmability

- SIMD parallelism in a DRAM mat is on par with vector ISAs' SIMD width

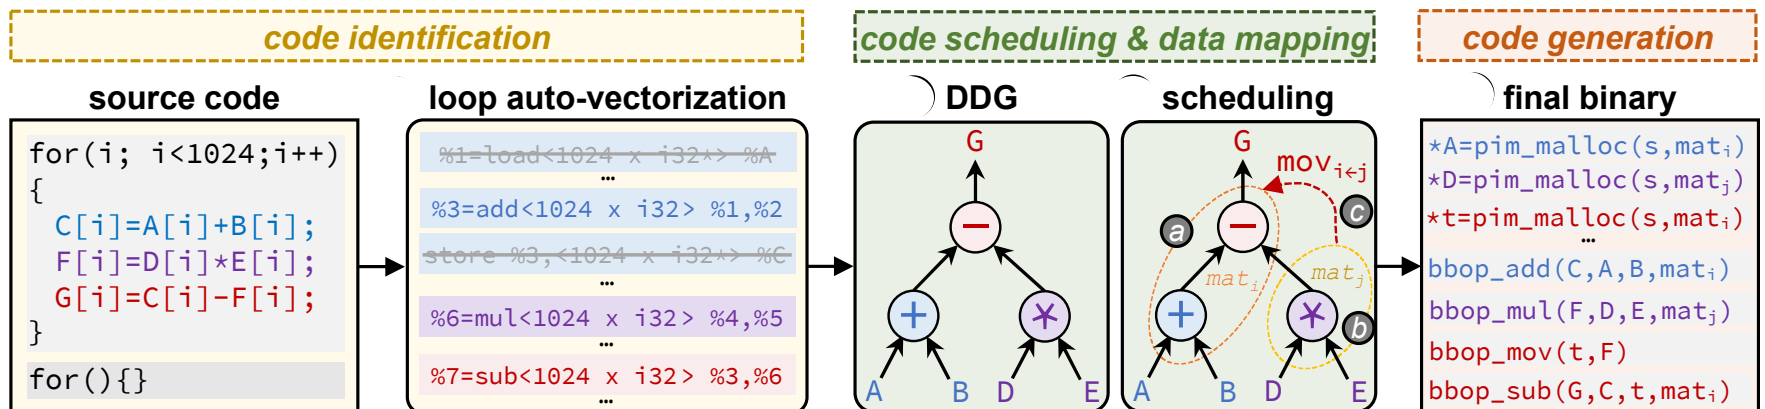

# MIMDRAM: Compiler Support

Goal

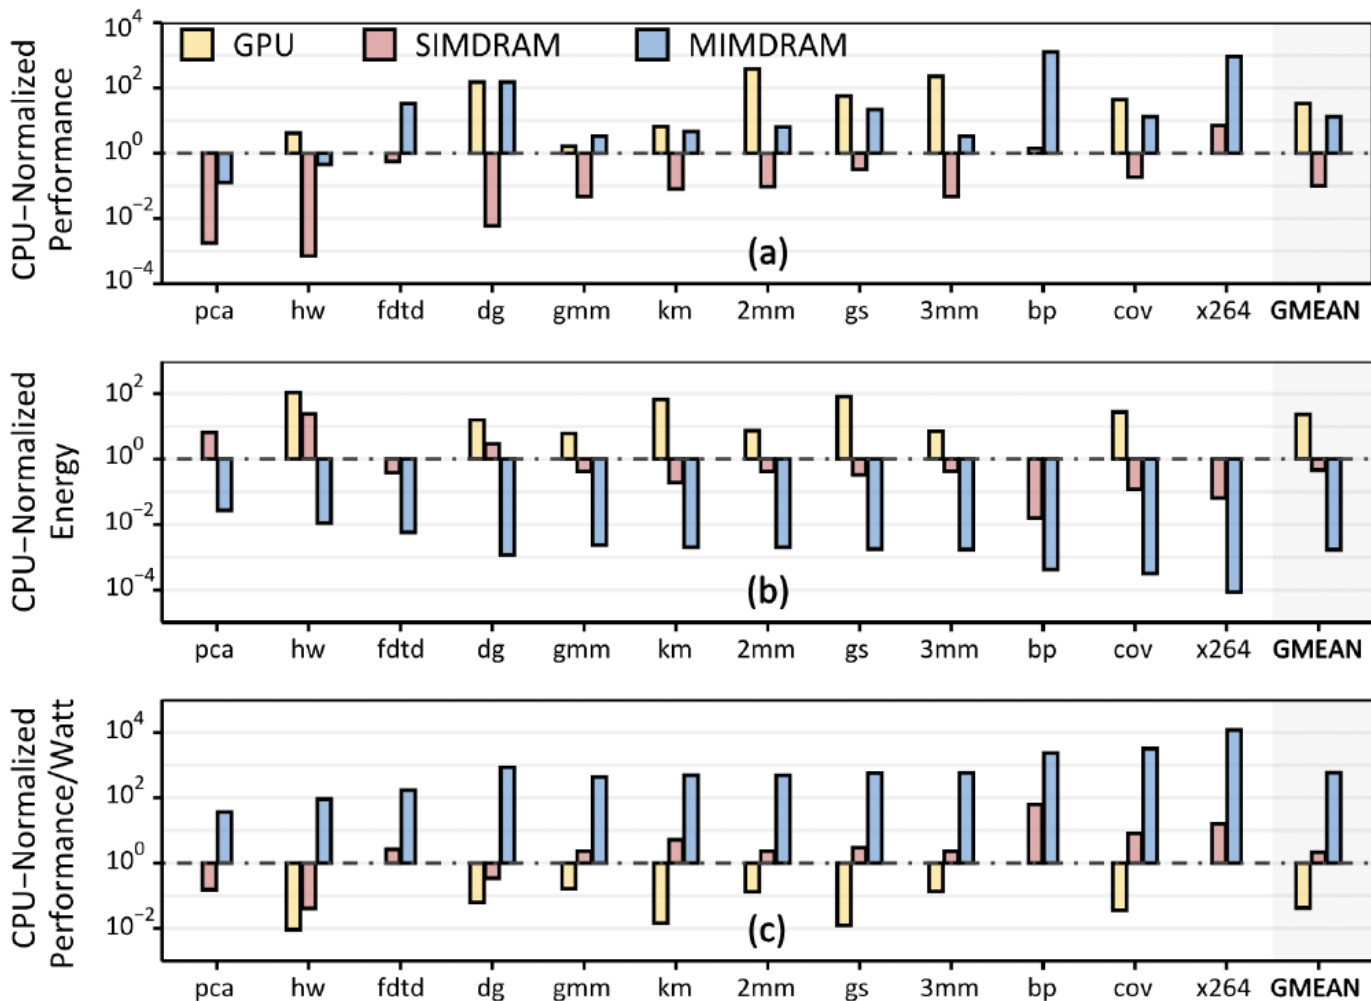

Transparently to programmer:  
extract SIMD parallelism from an application, and  
schedule PUD instructions while maximizing utilization

Three new LLVM-based passes targeting PUD execution

# MIMDRAM Perf, Energy, Perf/Watt

**582X and 13,612X the energy efficiency of CPU and GPU, respectively**

Existing DRAM Chips  
Are Already Quite Capable

# Real Processing Using Memory Prototype

---

- End-to-end RowClone & TRNG using off-the-shelf DRAM chips
- Idea: Violate DRAM timing parameters to mimic RowClone

# Real Processing-using-Memory Prototype

☰ README.md

## Building a PiDRAM Prototype

To build PiDRAM's prototype on Xilinx ZC706 boards, developers need to use the two sub-projects in this directory. `fpga-zynq` is a repository branched off of [UCB-BAR's fpga-zynq](#) repository. We use `fpga-zynq` to generate rocket chip designs that support end-to-end DRAM PuM execution. `controller-hardware` is where we keep the main Vivado project and Verilog sources for PiDRAM's memory controller and the top level system design.

## Rebuilding Steps

1. Navigate into `fpga-zynq` and read the README file to understand the overall workflow of the repository
  - Follow the readme in `fpga-zynq/rocket-chip/riscv-tools` to install dependencies
2. Create the Verilog source of the rocket chip design using the `ZynqCopyFPGAConfig`
  - Navigate into `zc706`, then run `make rocket CONFIG=ZynqCopyFPGAConfig -j<number of cores>`
3. Copy the generated Verilog file (should be under `zc706/src`) and overwrite the same file in `controller-hardware/source/hdl/impl/rocket-chip`
4. Open the Vivado project in `controller-hardware/Vivado_Project` using Vivado 2016.2
5. Generate a bitstream
6. Copy the bitstream (`system_top.bit`) to `fpga-zynq/zc706`
7. Use the `./build_script.sh` to generate the new `boot.bin` under `fpga-images-zc706`, you can use this file to program the FPGA using the SD-Card
  - For details, follow the relevant instructions in `fpga-zynq/README.md`

You can run programs compiled with the RISC-V Toolchain supplied within the `fpga-zynq` repository. To install the toolchain, follow the instructions under `fpga-zynq/rocket-chip/riscv-tools`.

## Generating DDR3 Controller IP sources

We cannot provide the sources for the Xilinx PHY IP we use in PiDRAM's memory controller due to licensing issues. We describe here how to regenerate them using Vivado 2016.2. First, you need to generate the IP RTL files:

- 1- Open IP Catalog
- 2- Find "Memory Interface Generator (MIG 7 Series)" IP and double click

<https://arxiv.org/pdf/2111.00082.pdf>

## Functionally-Complete Boolean Logic in Real DRAM Chips: Experimental Characterization and Analysis

İsmail Emir Yüksel    Yahya Can Tuğrul    Ataberk Olgun    F. Nisa Bostancı    A. Giray Yağlıkçı  
Geraldo F. Oliveira    Haocong Luo    Juan Gómez-Luna    Mohammad Sadrosadati    Onur Mutlu

ETH Zürich

*We experimentally demonstrate that COTS DRAM chips are capable of performing 1) functionally-complete Boolean operations: NOT, NAND, and NOR and 2) many-input (i.e., more than two-input) AND and OR operations. We present an extensive characterization of new bulk bitwise operations in 256 off-the-shelf modern DDR4 DRAM chips. We evaluate the reliability of these operations using a metric called success rate: the fraction of correctly performed bitwise operations. Among our 19 new observations, we highlight four major results. First, we can perform the NOT operation on COTS DRAM chips with 98.37% success rate on average. Second, we can perform up to 16-input NAND, NOR, AND, and OR operations on COTS DRAM chips with high reliability (e.g., 16-input NAND, NOR, AND, and OR with average success rate of 94.94%, 95.87%, 94.94%, and 95.85%, respectively). Third, data pattern only slightly*

# The Capability of COTS DRAM Chips

We demonstrate that COTS DRAM chips:

- 1 Can copy one row into up to 31 other rows with **>99.98%** success rate
- 2 Can perform **NOT operation** with up to **32 output operands**
- 3 Can perform up to **16-input AND, NAND, OR, and NOR** operations

# In-DRAM Multiple Row Copy (Multi-RowCopy)

Simultaneously activate many rows to copy **one row's content** to **multiple destination rows**

RowClone

Multi-RowCopy

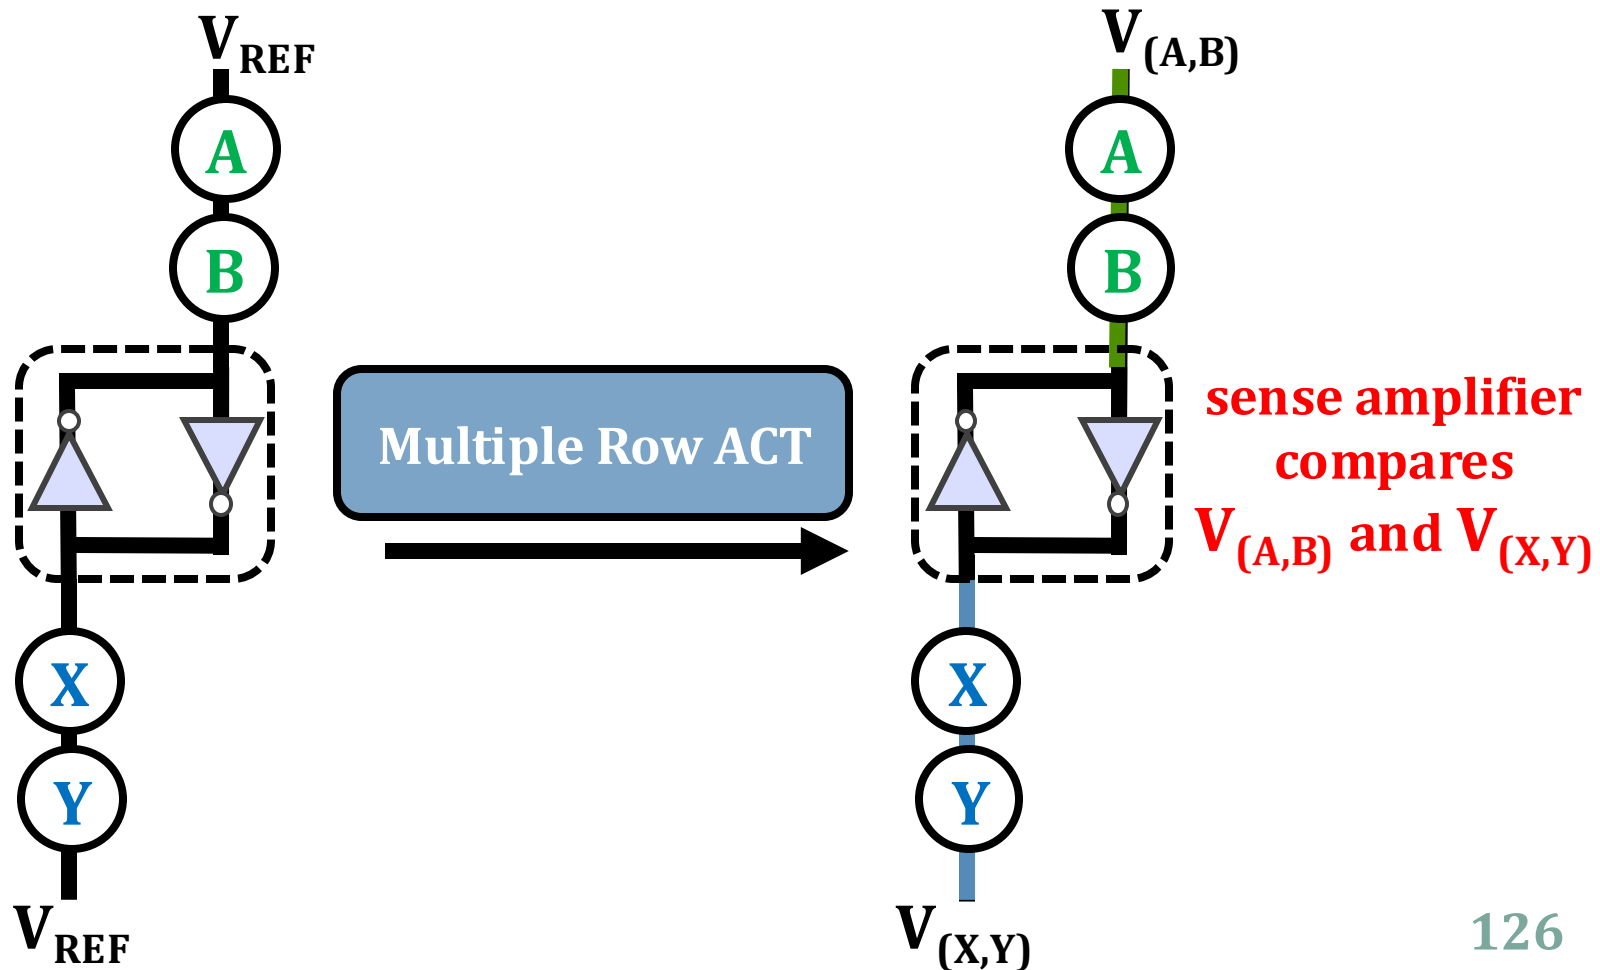

# Key Idea: NOT Operation

Connect rows in neighboring subarrays through a **NOT gate** by consecutively activating rows

# Key Idea: NAND, NOR, AND, OR

**Manipulate the bitline voltage** to express  
**a wide variety of functions** using  
simultaneous multi-row activation in neighboring subarrays

# Two-Input AND and NAND Operations

$V_{DD}=1$  &  $\text{GND} = 0$

X	Y	COM	REF
0	0	0	1
0	1	0	1
1	0	0	1
1	1	1	0
		AND	NAND

# Many-Input AND, NAND, OR, and NOR Operations

We can express AND, NAND, OR, and NOR operations by carefully manipulating the reference voltage

# In-DRAM TRNG: Recent Results

## ■ N-row Activation

- initialize cell values to sample random values in sense amplifiers

Fig. 11: **Throughput of generating true random numbers, as measured in 96 COTS DRAM chips using multiple-row activation, normalized to state-of-the-art DRAM-based TRNG, QUAC-TRNG (i.e., 4-row activation) [135].** Each error bar shows the range across all tested chips. We observe that random numbers that are generated with multiple-row activation and then post-processed with the SHA-256 function [221] pass *all* NIST STS tests [222], which means 2-, 4-, 8-, 16-, and 32-row activation generates high-quality true random bitstreams. On average, 8- and 16-row activation-based TRNG outperforms the state-of-the-art by  $1.25\times$  and  $1.06\times$ , respectively, while 2- and 32-row activation-based TRNG provides  $0.69\times$  and  $0.84\times$  the throughput of the state-of-the-art.

# Concluding Remarks

## Fundamentally Energy-Efficient (Data-Centric) Computing Architectures

# Fundamentally High-Performance **(Data-Centric)** Computing Architectures

# Computing Architectures with Minimal Data Movement

# Concluding Remarks

---

- Goal: Enable computation capability in memory
- We highlighted major recent advances in Processing-in-DRAM
  - ❑ Can lead to **orders-of-magnitude energy & perf** improvements
  - ❑ **Unmodified DRAM chips are already capable of computation**
- Memory should be designed as a **combined computation and storage substrate**
  - ❑ Not as an inactive storage substrate
  - ❑ Design mindset and flow should change
- Future of **truly memory-centric computing** is bright
  - ❑ We need to do research & design across the computing stack
  - ❑ With a proper mindset and infrastructure shift

**Data-centric**

**Data-driven**

**Data-aware**

Onur Mutlu

*ETH Zürich*

# SMD Key Idea: Autonomous Maintenance

DRAM chip controls in-DRAM maintenance operations

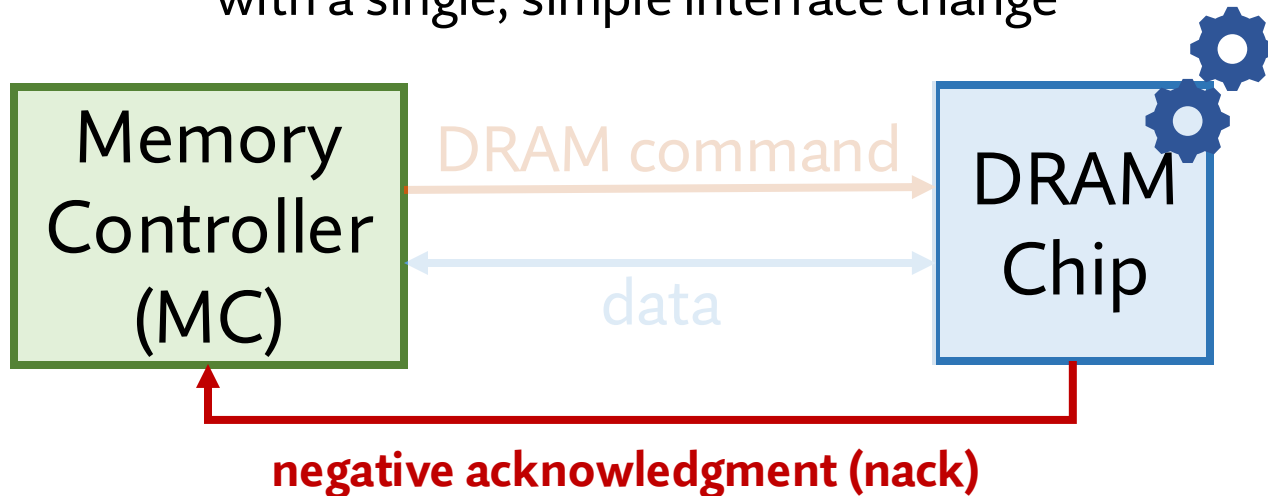

Enable implementing **new maintenance mechanisms** **without** modifying the standard and exposing **DRAM-internal proprietary** information

# SMD Key Contribution

DRAM chip controls in-DRAM maintenance operations

with a single, simple interface change

orchestrates  
all access operations

performs its own  
maintenance autonomously

**Partition the work nicely** between the memory controller and the DRAM chip

# SMD-Based Maintenance Mechanisms

## DRAM Refresh

### Fixed Rate (SMD-FR)

*uniformly* refreshes **all** DRAM rows with a **fixed** refresh period

### Variable Rate (SMD-VR)

*skips* refreshing rows that can **retain their data for longer** than the default refresh period

## RowHammer Protection

### Probabilistic (SMD-PRP)

Performs **neighbor** row refresh with a **small probability** on every row activation

### Deterministic (SMD-DRP)

*keeps track* of most **frequently activated** rows and performs **neighbor** row refresh when activation count threshold is exceeded

## Memory Scrubbing

### Periodic Scrubbing (SMD-MS)

periodically **scans** the **entire** DRAM for errors and corrects them

# Talk on Self-Managing DRAM

## Problem: The Rigid DRAM Interface

The **Memory Controller** manages DRAM maintenance operations

Changes to maintenance operations are often reflected to the memory controller design, DRAM interface, and other system components

Implementing new maintenance operations  
(or modifying the existing ones) is difficult-to-realize

### ALP: Alleviating CPU-Memory Data Movement Overheads in Memory-Centric Systems

Nika Mansouri Ghiasi, Nandita Vijaykumar, Geraldo F. Oliveira, Lois Orosa, Ivan Fernandez, Mohammad Sadrosadati, Konstantinos Kanellopoulos, Nastaran Hajinazar, Juan Gómez Luna, Onur Mutlu

**Abstract**—Recent advances in memory technology have enabled near-data processing (NDP) to tackle main memory bottlenecks in modern systems. Prior works partition applications into segments (e.g., instructions, loops, functions) and execute memory-bound segments of the applications on NDP computation units, while mapping the cache-friendly application segments to host CPU cores that access a deeper cache hierarchy. Partitioning applications between NDP and host cores causes inter-segment data movement overhead, which is the overhead from moving data generated from one segment and used in the consecutive segments. This overhead can be large if the segments map to cores in different parts of the system (i.e., host and NDP). Prior works take two approaches to the inter-segment data movement overhead when partitioning applications between NDP and host cores. The first class of works maps segments to NDP or host cores based on the properties of each segment, neglecting the performance impact of the inter-segment data movement. Such partitioning techniques suffer from inter-segment data movement overhead. The second class of works maps segments to host or NDP cores based on the overall memory bandwidth savings of each segment (which depends on the memory bandwidth savings within each segment and the inter-segment data movement overhead between other segments). These works do not offload each segment to the best-fitting core if they incur high inter-segment data movement overhead. Therefore these works miss some of the potential NDP performance benefits. We show that mapping each segment (here basic block) to its best-fitting core based on the properties of each segment, assuming no inter-segment data movement, can provide substantial performance benefits. However, we show that the inter-segment data movement reduces this benefit significantly.

To this end, we introduce ALP, a new programmer-transparent technique to leverage the performance benefits of NDP by *alleviating* the performance impact of inter-segment data movement between host and memory and enabling efficient partitioning of applications between host and NDP cores. ALP alleviates the inter-segment data movement overhead by *proactively and accurately* transferring the required data between the segments mapped on host and NDP cores. This is based on the key observation that the instructions that generate the inter-segment data stay the same across different executions of a program on different input sets. ALP uses a compiler pass to identify these instructions and uses specialized hardware support to transfer data between the host and NDP cores at runtime. Using both the compiler and runtime information, ALP efficiently maps application segments to either host or NDP cores considering 1) the properties of each segment, 2) the inter-segment data movement overhead between different segments, and 3) whether this inter-segment data movement overhead can be alleviated proactively and in a timely manner. We evaluate ALP across a wide range of workloads and show on average 54.3% and 45.4% speedup compared to executing the application only on the host CPU or only the NDP cores, respectively.

# Flash-Cosmos: Basic Ideas

## ■ Flash-Cosmos enables

- Computation on multiple operands with a single sensing operation
- Accurate computation results by eliminating raw bit errors in stored data

# Multi-Wordline Sensing (MWS): Bitwise AND

- Intra-Block MWS:

Simultaneously activates multiple WLs in the same block

→ Bitwise AND of the stored data in the WLs

A bitline reads as '1' only when all the target cells store '1'

→ Equivalent to the bitwise AND of all the target cells

Operate  
as a *resistance* (1)  
or an *open switch* (0)

WL<sub>2</sub>  
WL<sub>3</sub>  
WL<sub>4</sub>

Result: 0

0

0

0

BL<sub>1</sub>

BL<sub>2</sub>

BL<sub>3</sub>

BL<sub>4</sub>

# Multi-Wordline Sensing (MWS): Bitwise AND

- Intra-Block MWS:

Simultaneously activates multiple WLs in the same block

→ Bitwise AND of the stored data in the WLs

Flash-Cosmos (Intra-Block MWS) enables bitwise AND of multiple pages in the same block via a single sensing operation

# Other Types of Bitwise Operations

**Flash-Cosmos** also enables  
other types of bitwise operations  
(NOT/NAND/NOR/XOR/XNOR)  
leveraging **existing features** of NAND flash memory

## Flash-Cosmos: In-Flash Bulk Bitwise Operations Using Inherent Computation Capability of NAND Flash Memory

<https://arxiv.org/abs/2209.05566.pdf>

# Results: Real-Device Characterization

---

No changes to the cell array  
of commodity NAND flash chips

Can have many operands  
(AND: up to 48, OR: up to 4)  
with small increase in sensing latency (< 10%)

ESP significantly improves  
the reliability of computation results  
(no observed bit error in the tested flash cells)

# Results: Performance & Energy

Flash-Cosmos provides **significant performance & energy benefits** over all the baselines

The larger the number of operands,  
the higher the performance & energy benefits

# Flash-Cosmos: In-Flash Bulk Bitwise Execution

# Self-Managing DRAM

[MICRO 2024]

# SMD Key Idea: Autonomous Maintenance

DRAM chip controls in-DRAM maintenance operations

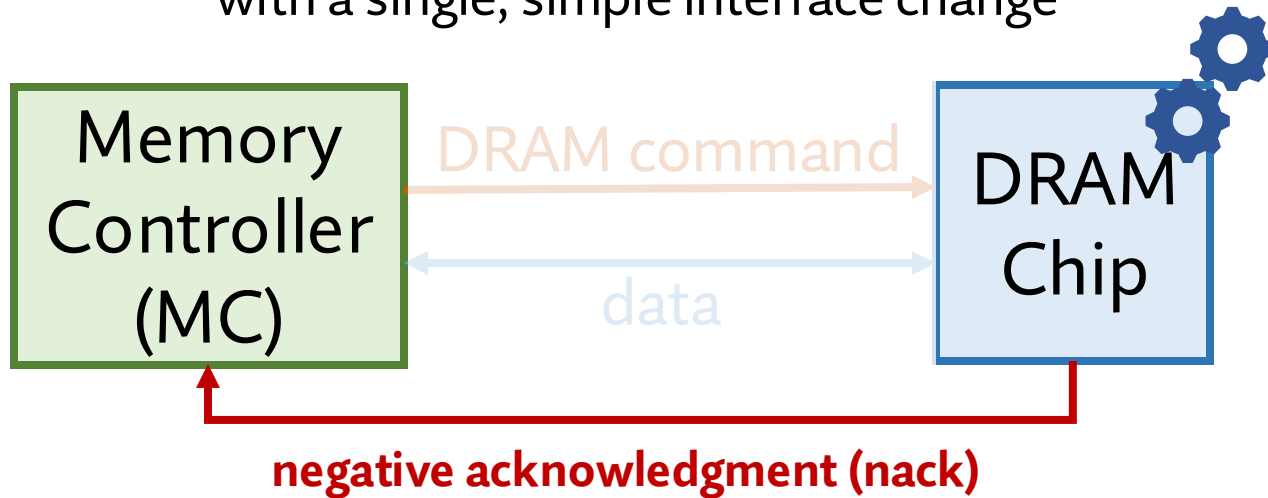

Enable implementing **new maintenance mechanisms** **without** modifying the standard and exposing **DRAM-internal proprietary** information

# SMD Key Contribution

DRAM chip controls in-DRAM maintenance operations

with a single, simple interface change

orchestrates  
all access operations

can now perform its own  
maintenance autonomously

**Partition the work nicely** between the memory controller and the DRAM chip

# PAPI LLM Inference System

[ASPLOS 2025]

# PAPI's Key Idea

Enable **online dynamic task scheduling** in a **heterogeneous PIM-enabled architecture** via online identification of kernel properties in LLM decoding

# PAPI's Key Components

A new PIM-enabled computing system design

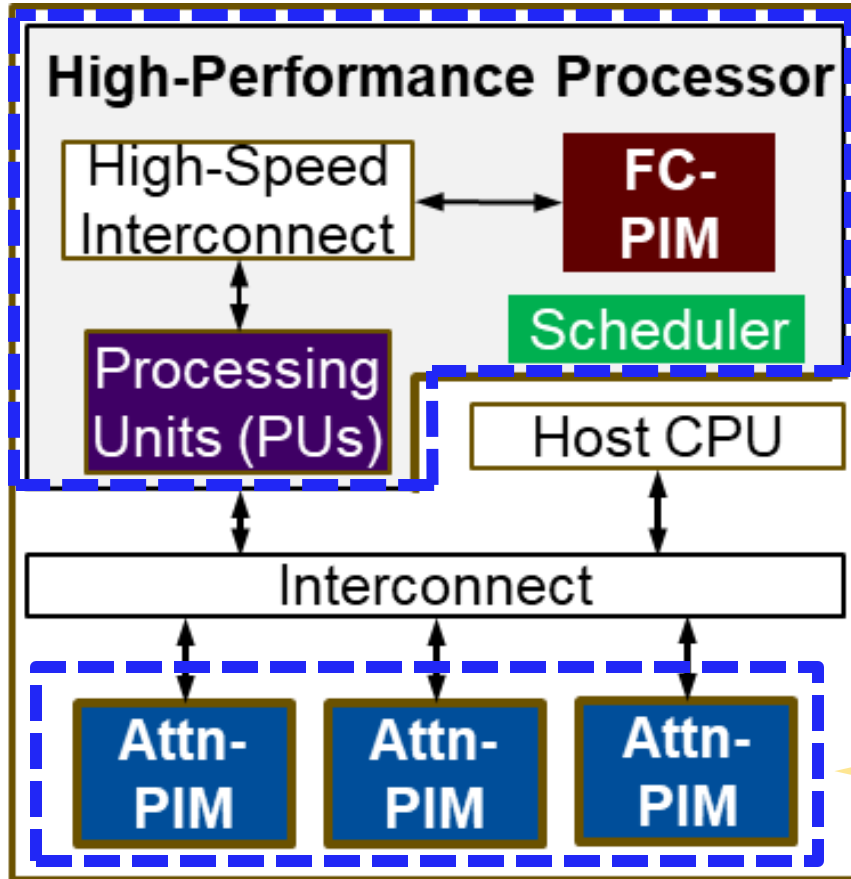

## Hybrid PIM units

to cater to different parallelism levels of FC and attention kernels

## Dynamic LLM kernel scheduling

to cater to dynamically changing parallelism levels

# PAPI's Architecture

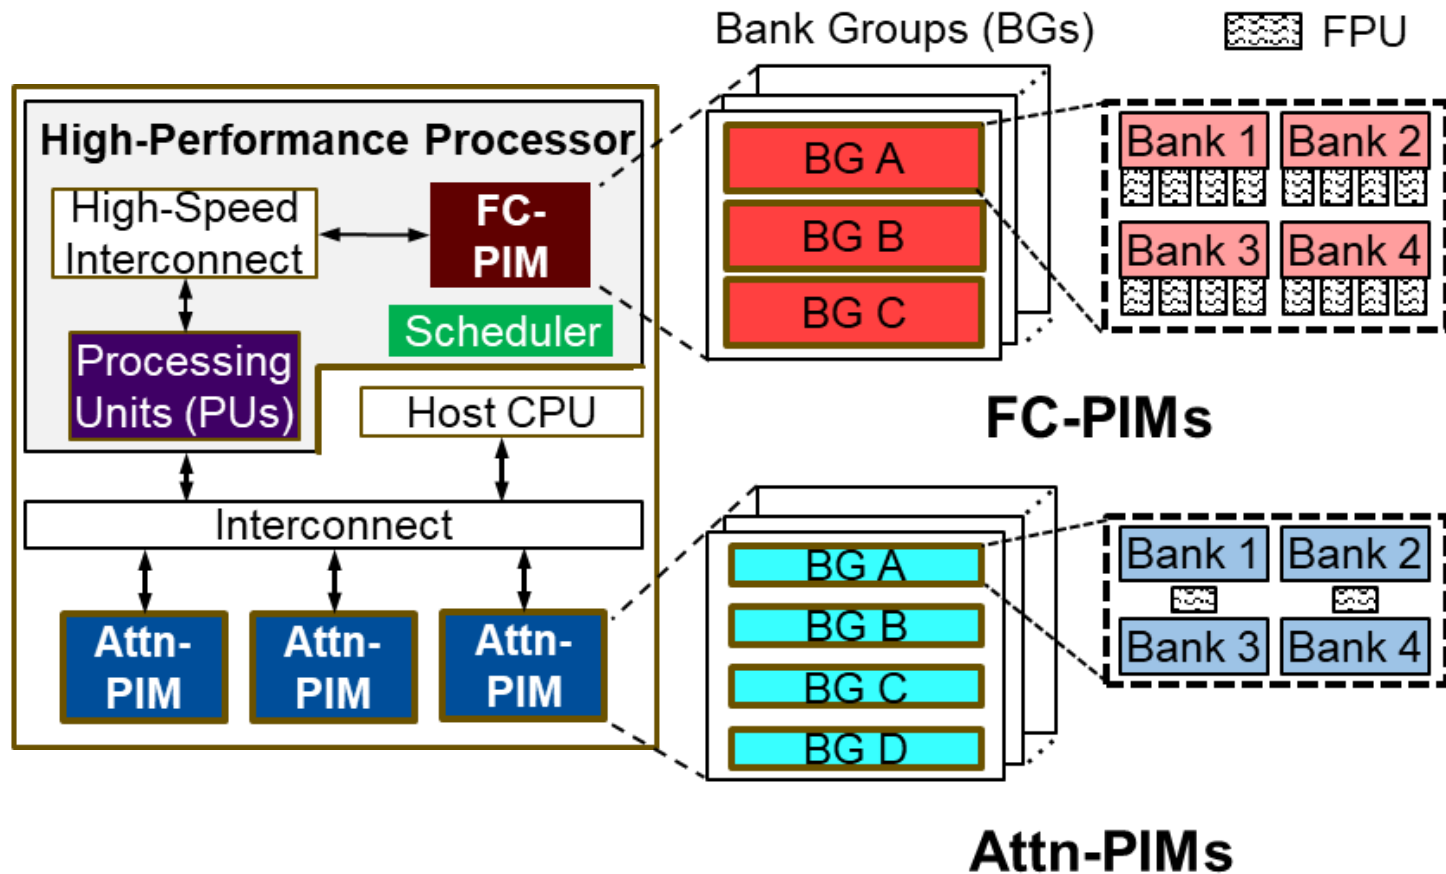

Handles memory-bound or compute-bound **FC kernels**

- Execution of FC kernels
- Dynamic scheduling

Handles memory-bound **attention kernels**

# PAPI's Architecture

**Hybrid PIM units** handle memory-bound FC & attention kernels with **different computational and memory demands**

# Outline

1 Background

2 Observations & Motivation

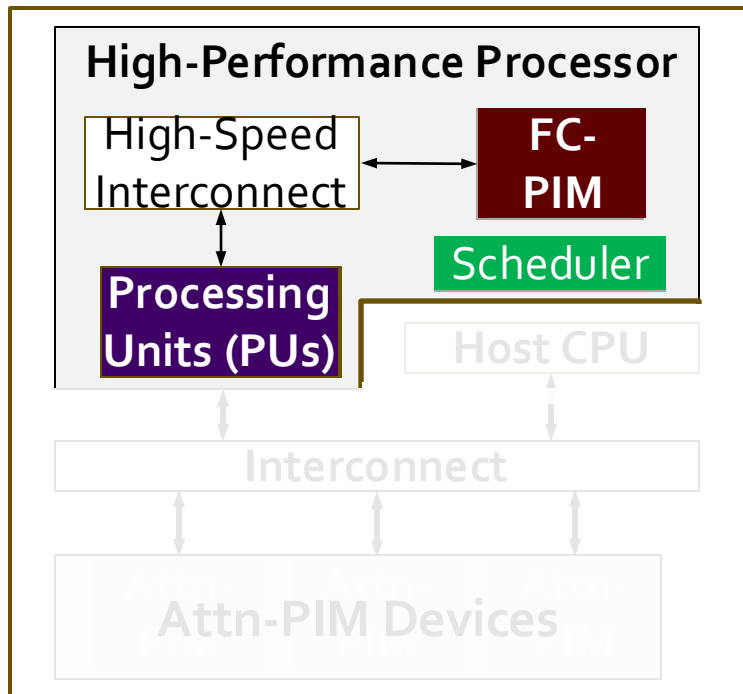

3 PAPI's Overview

**4 PAPI's Implementation**

5 Evaluation

6 Conclusion

# High-Performance Processor

**When FC kernels are compute-bound:**

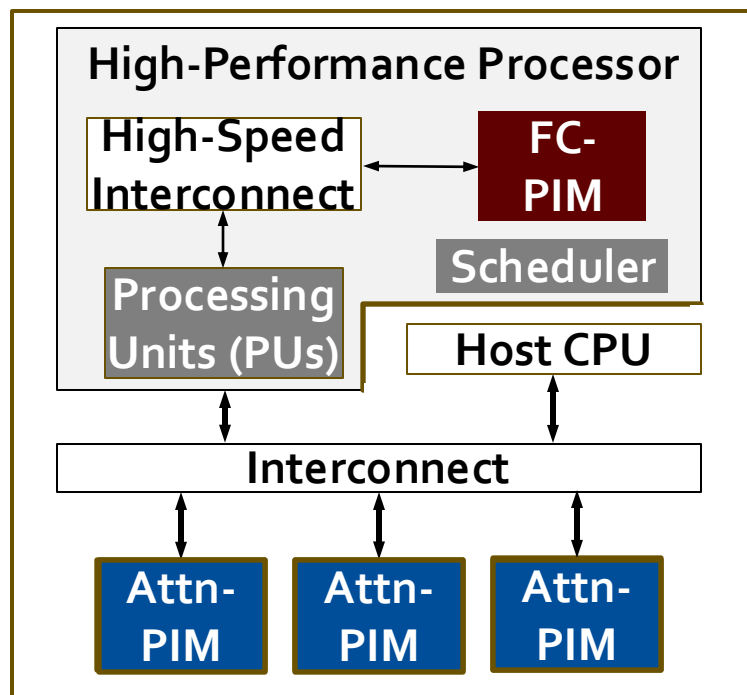

**Assign FC kernels to PUs**

**When FC kernels are memory-bound:**

**Assign FC kernels to FC-PIM**

# Hybrid PIM Units (I)

FC-PIM device placed in the High-Performance Processor

Attn-PIM devices store KV cache; separated from the High-Performance Processor

# Hybrid PIM Units (II)

 Floating-Point Processing Units (FPU)

Bank Groups (BGs)

FC-PIM

More FPUs per Bank

**Higher Computation Capability**  
to cater to FC kernels

Attn-PIMs

More Bank Groups per Stack  
More Attn-PIM Devices

**Higher Memory Capacity**  
to cater to attention kernels

# PAPI Runtime Scheduler

**Offline:** identify memory-boundedness threshold

## ① Monitor Parallelism Levels

- RLP & TLP

## ② Arithmetic Intensity Predictor

- Estimate arithmetic intensity of FC kernels
- Compare with memory-boundedness threshold

## ③ Schedule the FC Kernels

- Map FC kernels to either FC-PIM or PUs

# Evaluation Methodology

## Performance and Energy Analysis:

- Simulation using AttAcc [ASPLOS'24] and Ramulator 2 [IEEE CAL'23]

## Baselines:

- **AttAcc** [ASPLOS'24]
- **GPU+HBM-PIM** (NVIDIA A100 GPU + Samsung's HBM-PIM)
- **PIM-only** (PIM devices in AttAcc)

## Workloads: **Three** transformer-based LLMs

- LLaMA-65B, GPT-3 66B, GPT-3 175B

## Datasets: Dolly

- Creative-writing tasks
- General-QA tasks

# Performance Analysis

PAPI improves **performance** by **1.8X**, **1.9X**, and **11.1X** compared to AttAcc, GPU+HBM-PIM, and PIM-only, respectively

# Energy Analysis

AttAcc

GPU+HBM-PIM

PIM-only

PAPI

LLAMA-65B

GPT-3 66B

GPT-3 175B

PAPI improves **energy efficiency** by **3.4X**, **3.4X**, and **1.2X** compared to AttAcc, GPU+HBM-PIM, and PIM-only, respectively

# More in the Paper

- **Details on PAPI's implementation**
  - PAPI's heterogeneous architecture
  - PAPI's runtime scheduler
  - System integration
  - Data partitioning across PIM devices (both Attn-PIM & FC-PIM)
- **Detailed evaluation results**
  - PAPI's speedup across different RLP & TLP levels
  - Ablation study for PAPI's speedup
- **Area/power analysis**

# More in the Paper

## **PAPI: Exploiting Dynamic Parallelism in Large Language Model Decoding with a Processing-In-Memory-Enabled Computing System**

Yintao He<sup>1,2</sup> Haiyu Mao<sup>3,4</sup> Christina Giannoula<sup>5,6,4</sup> Mohammad Sadrosadati<sup>4</sup>  
Juan Gómez-Luna<sup>7</sup> Huawei Li<sup>1,2</sup> Xiaowei Li<sup>1,2</sup> Ying Wang<sup>1</sup> Onur Mutlu<sup>4</sup>

<sup>1</sup>SKLP, Institute of Computing Technology, CAS <sup>2</sup>University of Chinese Academy of Sciences <sup>3</sup>King's College London  
<sup>4</sup>ETH Zürich <sup>5</sup>University of Toronto <sup>6</sup>Vector Institute <sup>7</sup>NVIDIA

<https://arxiv.org/pdf/2502.15470>

# Conclusion

## Key Findings

- 1 LLM kernels have **different computation and memory bandwidth demands** across **different RLP & TLP levels**
- 2 **Memory-bound kernels** exhibit **different** computation demands depending on kernel type
- 3 LLM kernels have **dynamically changing** RLP and TLP levels

# Conclusion

## Key Contribution

### PAPI

A new **PIM-enabled heterogeneous** system design that caters to **varying demands** of LLM kernels by scheduling them **dynamically** to computation-centric processing units and hybrid PIM units

## Key Results

**PAPI** largely improves both performance and energy efficiency over best prior LLM decoding system

- **1.8×** speedup
- **3.4×** energy efficiency increase
